

REMARKS ON XIAO'S APPROACH OF SLOPE INEQUALITIES*

HAO SUN[†], XIAOTAO SUN[‡], AND MINGSHUO ZHOU[§]

Abstract. We prove the slope inequality for a relative minimal surface fibration in positive characteristic via Xiao's approach. We also prove a better low bound for the slope of non-hyperelliptic fibrations.

Key words. Slope inequality, surface fibration, non-hyperelliptic fibration, Harder-Narasimhan filtration, strongly semi-stable.

Mathematics Subject Classification. 14J25, 14Q10.

1. Introduction. Let S be a smooth projective surface over an algebraically closed field \mathbf{k} of characteristic $p \geq 0$ and $f : S \rightarrow B$ be a fibration with smooth general fiber F of genus g over a smooth projective curve B . Let $\omega_{S/B} := \omega_S \otimes f^*\omega_B^\vee$ be the relative canonical sheaf of f , and $K_{S/B} := K_S - f^*K_B$ be the relative canonical divisor. We say that f is relatively minimal if S contains no (-1) -curve in fibers. The following basic relative invariants are well known:

$$K_{S/B}^2 = (K_S - f^*K_B)^2 = K_S^2 - 8(g-1)(b-1), \\ \chi_f = \deg f_*\omega_{S/B} = \chi(\mathcal{O}_S) - (g-1)(b-1).$$

When f is relatively minimal and F is smooth, then $K_{S/B}$ is a nef divisor (see [11]). Under this assumption, the relative invariants satisfy the following remarkable so-called slope inequality.

THEOREM 1. *If f is relatively minimal, and the general fiber F is smooth, then*

$$K_{S/B}^2 \geq \frac{4(g-1)}{g} \chi_f. \quad (1.1)$$

When $\text{char}(\mathbf{k}) = 0$, this inequality was proved by Xiao (see [12]). For the case of semi-stable fibration, it was proved independently by Cornalba-Harris (see [2]). When $\text{char}(\mathbf{k}) = p > 0$, there exist a few approaches to prove this inequality (see [9], [13], etc). Some of them require the condition of semi-stable fibration.

In this note, we explain why Xiao's approach still works in the case of $\text{char}(\mathbf{k}) = p > 0$. Indeed, Xiao's approach is to study the Harder-Narasimhan filtration

$$0 = E_0 \subset E_1 \subset \cdots \subset E_n = E = f_*\omega_{S/B}$$

and give lower bound of $K_{S/B}^2$ in term of slop $\mu_i = \mu(E_i/E_{i-1})$. Here one of the key points is that semi-stability of E_i/E_{i-1} will imply nefness of \mathbb{Q} -divisors $\mathcal{O}_{\mathbb{P}(E_i)}(1) - \mu_i \Gamma_i$ where Γ_i is a fiber of $\mathbb{P}(E_i) \rightarrow B$. This is the only place one needs $\text{char}(\mathbf{k}) = 0$.

Our observation is that by a result of A. Langer there is an integer k_0 such that, when $k \geq k_0$, the Harder-Narasimhan filtration

$$0 = E_0 \subset E_1 \subset \cdots \subset E_n = E = F^{k*} f_* \omega_{S/B}$$

of $F^{k*} f_* \omega_{S/B}$ has strongly semi-stable E_i/E_{i-1} ($1 \leq i \leq n$) and that strongly semi-stability of E_i/E_{i-1} implies nefness of $\mathcal{O}_{\mathbb{P}(E_i)}(1) - \mu_i \Gamma_i$. When $f : S \rightarrow B$ is a semi-stable fibration, any Frobenius base change $F^k : B \rightarrow B$ induces fibration $\tilde{f} : \tilde{S} \rightarrow B$ such that

$$F^{k*} f_* \omega_{S/B} = \tilde{f}_* \omega_{\tilde{S}/B}, \quad \frac{K_{S/B}^2}{\deg f_* \omega_{S/B}} = \frac{K_{\tilde{S}/B}^2}{\deg \tilde{f}_* \omega_{\tilde{S}/B}}.$$

Thus for semi-stable fibration $f : S \rightarrow B$ we can assume (without loss of generality) that all E_i/E_{i-1} appearing in Harder-Narasimhan filtration of $E = f_* \omega_{S/B}$ are strongly semi-stable. Then Xiao's approach works for $\text{char}(\mathbf{k}) = p > 0$ without any modification. We will show in this note that a slightly modification of Xiao's approach works for any fibration $f : S \rightarrow B$. In fact, we will prove the following more general result holds for $\text{char}(\mathbf{k}) = p \geq 0$.

THEOREM 2. *Let D be a relative nef divisor on $f : S \rightarrow B$ such that $D|_F$ is generated by global sections on a general smooth fiber F of $f : S \rightarrow B$. Assume that $D|_F$ is a special divisor on F and*

$$A = 2h^0(D|_F) - D \cdot F - 1 > 0.$$

Then

$$D^2 \geq \frac{2D \cdot F}{h^0(D|_F)} \deg(f_* \mathcal{O}_S(D)).$$

Xiao also constructed examples (cf.[12, Example 2]) of hyperelliptic fibration $f : S \rightarrow B$ such that

$$K_{S/B}^2 = \frac{4g-4}{g} \deg(f_* \omega_{S/B})$$

and conjectured (cf. [12, Conjecture 1]) that the inequality must be strict for non-hyperelliptic fibrations, i.e., the general fiber F of f is a non-hyperelliptic curve, which was proved by Konno [4, Proposition 2.6]. Lu and Zuo [7] obtained a sharp slope inequality for non-hyperelliptic fibrations, which was generalized to $\text{char}(\mathbf{k}) = p > 0$ in [6] for a non-hyperelliptic semi-stable fibration.

Here we also remark that our previous observation can be used to prove the following theorem in any characteristic easily.

THEOREM 3. *Assume that $f : S \rightarrow B$ is a relatively minimal non-hyperelliptic surface fibration over an algebraically closed field of any characteristic, and the general fiber of f is smooth. Then*

$$K_{S/B}^2 \geq \min\left\{\frac{9(g-1)}{2(g+1)}, 4\right\} \deg f_* \omega_{S/B}. \tag{1.3}$$

Our article is organized as follows. In Section 2, we give a generalization of Xiao's approach, and show that a slightly modification of Xiao's approach works in any characteristic. In Section 3, we prove Theorem 3 via the modification of Xiao's approach and the modified second multiplication map $F^{k*}S^2f_*\omega_{S/B} \rightarrow F^{k*}f_*(\omega_{S/B}^{\otimes 2})$.

2. Xiao's approach and its generalization. We start from an elementary (but important) lemma due to Xiao.

LEMMA 1 ([12, Lemma 2]). *Let $f : S \rightarrow B$ be a relatively minimal fibration, with a general fiber F . Let D be a divisor on S , and suppose that there are a sequence of effective divisors*

$$Z_1 \geq Z_2 \geq \cdots \geq Z_n \geq Z_{n+1} = 0$$

and a sequence of rational numbers

$$\mu_1 > \mu_2 \cdots > \mu_n, \quad \mu_{n+1} = 0$$

such that for every i , $N_i = D - Z_i - \mu_i F$ is a nef \mathbb{Q} -divisor. Then

$$D^2 \geq \sum_{i=1}^n (d_i + d_{i+1})(\mu_i - \mu_{i+1}),$$

where $d_i = N_i \cdot F$.

Proof. Since $N_{i+1} = N_i + (\mu_i - \mu_{i+1})F + (Z_i - Z_{i+1})$, we have

$$\begin{aligned} N_{i+1}^2 &= N_{i+1}N_i + d_{i+1}(\mu_i - \mu_{i+1}) + N_{i+1}(Z_i - Z_{i+1}) \\ &= N_i^2 + (d_i + d_{i+1})(\mu_i - \mu_{i+1}) + (N_i + N_{i+1})(Z_i - Z_{i+1}) \\ &\geq N_i^2 + (d_i + d_{i+1})(\mu_i - \mu_{i+1}). \end{aligned}$$

Thus $N_{i+1}^2 - N_i^2 \geq (d_i + d_{i+1})(\mu_i - \mu_{i+1})$ and

$$D^2 = N_{n+1}^2 = N_1^2 + \sum_{i=1}^n (N_{i+1}^2 - N_i^2) \geq \sum_{i=1}^n (d_i + d_{i+1})(\mu_i - \mu_{i+1}).$$

□

We need some well-known facts about vector bundles on curves. Let B be a smooth projective curve over \mathbf{k} , for a vector bundle E on B , the slope of E is defined to be

$$\mu(E) = \frac{\deg E}{\text{rk}(E)}$$

where $\text{rk}(E)$, $\deg E$ denote the rank and degree of E (respectively). Recall that E is said to be semi-stable (resp., stable) if for any nontrivial subbundle $E' \subsetneq E$, we have

$$\mu(E') \leq \mu(E) \quad (\text{resp.}, <).$$

If E is not semi-stable, one has the following well-known theorem

THEOREM 4 (Harder-Narasimhan filtration). *For any vector bundle E on B , there is a unique filtration*

$$0 := E_0 \subset E_1 \subset \cdots \subset E_n = E$$

which is the so called Harder-Narasimhan filtration, such that

- (1) each quotient E_i/E_{i-1} is semi-stable for $1 \leq i \leq n$,
- (2) $\mu_1 > \dots > \mu_n$, where $\mu_i := \mu(E_i/E_{i-1})$ for $1 \leq i \leq n$.

The rational numbers $\mu_{\max}(E) := \mu_1$ and $\mu_{\min}(E) := \mu_n$ are important invariants of E . Let $\pi : \mathbb{P}(E) \rightarrow B$ be projective bundle and $\pi^*E \rightarrow \mathcal{O}_E(1) \rightarrow 0$ be the tautological quotient line bundle. Then the following lemma (which was proved by Xiao in another formulation) relating semi-stability of E with nefness of $\mathcal{O}_E(1)$ only holds when $\text{char}(\mathbf{k}) = 0$.

LEMMA 2 ([8, Theorem 3.1], See also [12, Lemma 3]). *Let Γ be a fiber of $\pi : \mathbb{P}(E) \rightarrow B$. Then*

$$\mathcal{O}_E(1) - \mu_{\min}(E)\Gamma$$

is a nef \mathbb{Q} -divisor. In particular, for each sub-bundle E_i in Harder-Narasimhan filtration of E , the divisor

$$\mathcal{O}_{E_i}(1) - \mu_i\Gamma_i$$

is a nef \mathbb{Q} -divisor, where Γ_i is a fiber of $\mathbb{P}(E_i) \rightarrow B$.

THEOREM 5. *Let D be a relative nef divisor on $f : S \rightarrow B$ such that $D|_F$ is generated by global sections on a general smooth fiber F of $f : S \rightarrow B$. Assume that $D|_F$ is a special divisor on F and*

$$A = 2h^0(D|_F) - D \cdot F - 1 > 0.$$

Then

$$D^2 \geq \frac{2D \cdot F}{h^0(D|_F)} \deg(f_*\mathcal{O}_S(D)).$$

Proof. For a divisor D on $f : S \rightarrow B$, $E = f_*\mathcal{O}_S(D)$ is a vector bundle of rank $h^0(D|_F)$ where F is a general smooth fiber of $f : S \rightarrow B$. Let

$$0 := E_0 \subset E_1 \subset \dots \subset E_n = E$$

be the Harder-Narasimhan filtration of E with $r_i = \text{rk}(E_i)$ and

$$\mu_i = \mu(E_i/E_{i-1}) = \mu_{\min}(E_i) \quad (1 \leq i \leq n).$$

Let $\mathcal{L}_i \subset \mathcal{O}_S(D)$ be the image of f^*E_i under sheaf homomorphism

$$f^*E_i \hookrightarrow f^*E = f^*f_*\mathcal{O}_S(D) \rightarrow \mathcal{O}_S(D),$$

which is a torsion-free sheaf of rank 1 and is locally free on an open set $U_i \subset S$ of codimension at least 2. Thus there is a morphism (over B)

$$\phi_i : U_i \rightarrow \mathbb{P}(E_i)$$

such that $\phi_i^*\mathcal{O}_{E_i}(1) = \mathcal{L}_i|_{U_i}$, which implies that $c_1(\mathcal{L}_i) - \mu_i F$ is nef by Lemma 2. Let $D = c_1(\mathcal{L}_i) + Z_i$ ($1 \leq i \leq n$). Then we get a sequence of effective divisors

$Z_1 \geq Z_2 \geq \cdots \geq Z_n \geq 0$ and a sequence of rational numbers $\mu_1 > \mu_2 \cdots > \mu_n$ such that

$$N_i = D - Z_i - \mu_i F \quad (1 \leq i \leq n)$$

are nef \mathbb{Q} -divisors. Note $N_i|_F = c_1(\mathcal{L}_i)|_F \hookrightarrow D|_F$, one has surjection

$$H^1(N_i|_F) \twoheadrightarrow H^1(D|_F).$$

Thus $N_i|_F$ is special since $D|_F$ is special, and

$$d_i = N_i \cdot F \geq 2h^0(\mathcal{L}_i|_F) - 2 = 2r_i - 2, \quad (i = 1, \dots, n)$$

by Clifford theorem. Since $D|_F$ is generated by global sections, Z_n is supported on fibers of $f : S \rightarrow B$ and $d_n = D \cdot F := d_{n+1}$.

When $n = 1$, we have $D^2 = N_1^2 + (D + N_1) \cdot Z_1 + 2\mu_1 D \cdot F$ and

$$D^2 \geq 2\mu_1 D \cdot F = \frac{2D \cdot F}{h^0(D|_F)} \deg(f_* \mathcal{O}_S(D))$$

since Z_1 is supported on fibers of $f : S \rightarrow B$ and D is a relative nef divisor. When $n > 1$, by the same reason,

$$D^2 = N_n^2 + 2\mu_n D \cdot F + (N_n + D) \cdot Z_n \geq N_n^2 + 2\mu_n D \cdot F$$

and, by using Lemma 1 to N_n^2 , we have

$$\begin{aligned} D^2 &\geq \sum_{i=1}^{n-1} (d_i + d_{i+1})(\mu_i - \mu_{i+1}) + 2\mu_n D \cdot F \\ &\geq \sum_{i=1}^{n-1} (2r_i + 2r_{i+1} - 4)(\mu_i - \mu_{i+1}) + 2\mu_n D \cdot F \\ &\geq \sum_{i=1}^{n-1} (4r_i - 2)(\mu_i - \mu_{i+1}) + 2\mu_n D \cdot F \\ &= 4 \sum_{i=1}^n r_i (\mu_i - \mu_{i+1}) - 2\mu_1 - (4h^0(D|_F) - 2D \cdot F - 2)\mu_n \\ &= 4\deg(f_* \mathcal{O}_S(D)) - 2\mu_1 - 2A\mu_n \end{aligned}$$

where we use the equality (which is easy to check) that

$$\deg(f_* \mathcal{O}_S(D)) = \sum_{i=1}^n r_i (\mu_i - \mu_{i+1}).$$

Again by $D^2 = N_n^2 + 2\mu_n D \cdot F + (N_n + D) \cdot Z_n$, apply Lemma 1 to $(Z_1 \geq Z_n \geq 0, \mu_1 > \mu_n)$, we have

$$D^2 \geq (d_1 + D \cdot F)(\mu_1 - \mu_n) + 2D \cdot F\mu_n \geq D \cdot F(\mu_1 + \mu_n).$$

By using above two inequalities and eliminating μ_1 , we have

$$(2 + D \cdot F)D^2 - 4D \cdot F\deg(f_* \mathcal{O}_S(D)) \geq -2(A - 1)D \cdot F\mu_n.$$

By eliminating μ_n (which is possible since we assume $A > 0$), we have

$$(2A + D \cdot F)D^2 - 4D \cdot F \deg(f_* \mathcal{O}_S(D)) \geq 2(A - 1)D \cdot F \mu_1.$$

By adding above two inequalities and using definition of A , we have

$$4h^0(D|_F)D^2 - 8D \cdot F \deg(f_* \mathcal{O}_S(D)) \geq 2(A - 1)D \cdot F(\mu_1 - \mu_n) \geq 0$$

which is what we want. \square

COLLOARY 1 (Xiao's inequality). *Let $f : S \rightarrow B$ be a relatively minimal fibration of genus $g \geq 2$. Then*

$$K_{S/B}^2 \geq \frac{4g - 4}{g} \deg(f_* \omega_{S/B}).$$

Proof. Take $D = K_{S/B}$ (the relative canonical divisor), which satisfies all the assumptions in Theorem 5 with $h^0(D|_F) = g$, $D \cdot F = 2g - 2$ and $\mathcal{O}_S(D) = \omega_{S/B}$. \square

The only obstruction to generalize Xiao's method in positive characteristic is Lemma 2, which is not true in positive characteristic since Frobenius pull-back of a semi-stable bundle may not be semi-stable. However, the following notion of strongly semi-stability has nice property that pull-back under a finite map preserves strongly semi-stability.

DEFINITION 1. *The bundle E is called strongly semi-stable (resp., stable) if its pullback by k -th power F^k is semi-stable (resp., stable) for any integer $k \geq 0$, where F is the Frobenius morphism $B \rightarrow B$.*

LEMMA 3 ([5, Theorem 3.1]). *For any bundle E on B , there exists an integer k_0 such that all of quotients E_i/E_{i-1} ($1 \leq i \leq n$) appear in the Harder-Narasimhan filtration*

$$0 := E_0 \subset E_1 \subset \cdots \subset E_n = F^{k*} E$$

are strongly semi-stable whenever $k \geq k_0$.

LEMMA 4. *For each sub-bundle E_i in the Harder-Narasimhan filtration*

$$0 := E_0 \subset E_1 \subset \cdots \subset E_n = F^{k*} E$$

of $F^{k} E$ (when $k \geq k_0$), the divisor $\mathcal{O}_{E_i}(1) - \mu_i \Gamma_i$ is a nef \mathbb{Q} -divisor, where Γ_i is a fiber of $\mathbb{P}(E_i) \rightarrow B$ and $\mu_i = \mu(E_i/E_{i-1})$.*

Proof. The proof is just a modification of [8, Theorem 3.1] since pull-back of strongly semi-stable bundles under a finite morphism are still strongly semi-stable. One can see [8, Theorem 3.1, Page 464] for more details. \square

We now can prove, by the same arguments, that Theorem 5 still holds in positive characteristic.

THEOREM 6. *Let D be a relative nef divisor on $f : S \rightarrow B$ such that $D|_F$ is generated by global sections on a general smooth fiber F of $f : S \rightarrow B$. Assume that $D|_\Gamma$ is a special divisor on F and*

$$A = 2h^0(D|_F) - D \cdot F - 1 > 0.$$

Then

$$D^2 \geq \frac{2D \cdot F}{h^0(D|_F)} \deg(f_* \mathcal{O}_S(D)).$$

Proof. It is enough to prove the theorem when $f : S \rightarrow B$ is defined over a base field \mathbf{k} of characteristic $p > 0$. Let $F_S : S \rightarrow S$ denote the Frobenius morphism over \mathbf{k} . Then we have the following commutative diagram (for any integer $k \geq k_0$):

$$\begin{array}{ccc} S & \xrightarrow{F_S^k} & S \\ f \downarrow & & \downarrow f \\ B & \xrightarrow{F^k} & B \end{array} .$$

For a divisor D on $f : S \rightarrow B$, $E = f_* \mathcal{O}_S(D)$ is a vector bundle of rank $h^0(D|_F)$ where F is a general smooth fiber of $f : S \rightarrow B$. Let

$$0 := E_0 \subset E_1 \subset \cdots \subset E_n = F^{k*} E$$

be the Harder-Narasimhan filtration of $F^{k*} E$ with $r_i = \text{rk}(E_i)$ and

$$\mu_i = \mu(E_i/E_{i-1}) = \mu_{\min}(E_i) \quad (1 \leq i \leq n)$$

where we choose $k \geq k_0$ such that all quotients E_i/E_{i-1} appears in above filtration are strongly semi-stable.

Let $\mathcal{L}_i \subset F_S^{k*} \mathcal{O}_S(D)$ be the image of $f^* E_i$ under sheaf homomorphism

$$f^* E_i \hookrightarrow f^* F^{k*} E = F_S^{k*} f^* f_* \mathcal{O}_S(D) \rightarrow F_S^{k*} \mathcal{O}_S(D) = \mathcal{O}_S(p^k D),$$

which is a torsion-free sheaf of rank 1 and is locally free on an open set $U_i \subset S$ of codimension at least 2. Thus there is a morphism (over B)

$$\phi_i : U_i \rightarrow \mathbb{P}(E_i)$$

such that $\phi_i^* \mathcal{O}_{E_i}(1) = \mathcal{L}_i|_{U_i}$, which implies that $c_1(\mathcal{L}_i) - \mu_i F$ is nef by Lemma 4. Let $p^k D = c_1(\mathcal{L}_i) + Z_i$ ($1 \leq i \leq n$). Then we get a sequence of effective divisors $Z_1 \geq Z_2 \geq \cdots \geq Z_n \geq 0$ and a sequence of rational numbers $\mu_1 > \mu_2 \cdots > \mu_n$ such that

$$N_i = p^k D - Z_i - \mu_i F \quad (1 \leq i \leq n)$$

are nef \mathbb{Q} -divisors. Let $d_i = N_i \cdot F = \deg(\mathcal{L}_i|_F)$, then

$$d_n = p^k D \cdot F := d_{n+1}$$

since $D|_F$ is generated by global sections and Z_n is supported on fibers of $f : S \rightarrow B$. For $1 \leq i < n$, there are $r_i = \text{rk}(E_i)$ sections

$$\{s_1, \dots, s_{r_i}\} \in H^0(\mathcal{O}_S(D)|_F)$$

such that $\mathcal{L}_i|_F \subset \mathcal{O}_S(p^k D)|_F$ is generated by the global sections $s_1^{p^k}, \dots, s_{r_i}^{p^k}$.

Since $\mathcal{O}_S(D)|_F$ is special, the sub-sheaf $L_i \subset \mathcal{O}_S(D)|_F$ generated by

$$\{s_1, \dots, s_{r_i}\} \in H^0(\mathcal{O}_S(D)|_F)$$

is special. Thus $\deg(L_i) \geq 2r_i - 2$ by Clifford theorem. Then we have

$$d_i = N_i \cdot F = \deg(\mathcal{L}_i|_F) = p^k \deg(L_i) \geq p^k(2r_i - 2) \quad (1 \leq i \leq n).$$

When $n = 1$, which means that $E = f_*\mathcal{O}_S(D)$ is strongly semi-stable, the same proof of Theorem 5 implies

$$D^2 \geq 2\mu_1 D \cdot F = \frac{2D \cdot F}{h^0(D|_F)} \deg(f_*\mathcal{O}_S(D)).$$

When $n > 1$, since Z_n is supported on fibers of $f : S \rightarrow B$, we have

$$p^{2k}D^2 = N_n^2 + 2\mu_n p^k D \cdot F + (N_n + p^k D) \cdot Z_n \geq N_n^2 + 2\mu_n p^k D \cdot F.$$

By $d_i \geq p^k(2r_i - 2)$ and using Lemma 1 to N_n^2 , we have

$$\begin{aligned} p^{2k}D^2 &\geq \sum_{i=1}^{n-1} (d_i + d_{i+1})(\mu_i - \mu_{i+1}) + 2\mu_n p^k D \cdot F \\ &\geq \sum_{i=1}^{n-1} p^k(2r_i + 2r_{i+1} - 4)(\mu_i - \mu_{i+1}) + 2\mu_n p^k D \cdot F \\ &\geq p^k \sum_{i=1}^{n-1} (4r_i - 2)(\mu_i - \mu_{i+1}) + 2\mu_n p^k D \cdot F \\ &= 4p^k \sum_{i=1}^n r_i(\mu_i - \mu_{i+1}) - 2p^k \mu_1 - p^k(4h^0(D|_F) - 2D \cdot F - 2)\mu_n \\ &= 4p^k \deg(F^{k*}f_*\mathcal{O}_S(D)) - 2p^k \mu_1 - 2p^k A\mu_n \end{aligned}$$

where we set $\mu_{n+1} = 0$ and use the equality (which is easy to check)

$$\deg(F^{k*}f_*\mathcal{O}_S(D)) = \sum_{i=1}^n r_i(\mu_i - \mu_{i+1}).$$

By $p^{2k}D^2 = N_n^2 + 2\mu_n p^k D \cdot F + (N_n + p^k D) \cdot Z_n$, apply Lemma 1 to $(Z_1 \geq Z_n \geq 0, \mu_1 > \mu_n)$, we have

$$p^{2k}D^2 \geq (d_1 + p^k D \cdot F)(\mu_1 - \mu_n) + 2p^k D \cdot F \mu_n \geq p^k D \cdot F(\mu_1 + \mu_n).$$

Altogether, we have the following inequalities

$$p^k D^2 \geq 4\deg(F^{k*}f_*\mathcal{O}_S(D)) - 2\mu_1 - 2A\mu_n \tag{2.1}$$

$$p^k D^2 \geq D \cdot F(\mu_1 + \mu_n) \tag{2.2}$$

By using (2.1) and (2.2), eliminating μ_1 , we have

$$(2 + D \cdot F)p^k D^2 - 4D \cdot F \deg(F^{k*}f_*\mathcal{O}_S(D)) \geq -2(A - 1)D \cdot F \mu_n$$

By eliminating μ_n (which is possible since we assume $A > 0$), we have

$$(2A + D \cdot F)p^k D^2 - 4D \cdot F \deg(F^{k*} f_* \mathcal{O}_S(D)) \geq 2(A-1)D \cdot F \mu_1.$$

By adding above two inequalities and using definition of A , we have

$$4h^0(D|_F)p^k D^2 - 8\deg(F^{k*} f_* \mathcal{O}_S(D)) \geq 2(A-1)D \cdot F(\mu_1 - \mu_n) \geq 0$$

which and $\deg(F^{k*} f_* \mathcal{O}_S(D)) = p^k \deg(f_* \mathcal{O}_S(D))$ imply

$$D^2 \geq \frac{2D \cdot F}{h^0(D|_F)} \deg(f_* \mathcal{O}_S(D)).$$

□

COLLOARY 2. *Let $f : S \rightarrow B$ be a relatively minimal fibration of genus $g \geq 2$ over an algebraically closed field of characteristic $p \geq 0$. Then*

$$K_{S/B}^2 \geq \frac{4g-4}{g} \deg(f_* \omega_{S/B}).$$

Proof. Take $D = K_{S/B}$ (the relative canonical divisor), which satisfies all the assumptions in Theorem 6 with $h^0(D|_F) = g$, $D \cdot F = 2g-2$ and $\mathcal{O}_S(D) = \omega_{S/B}$. □

3. Slopes of non-hyperelliptic fibrations. Xiao has constructed examples (cf.[12, Example 2]) of hyperelliptic fiberation $f : S \rightarrow B$ such that

$$K_{S/B}^2 = \frac{4g-4}{g} \deg(f_* \omega_{S/B})$$

and has conjectured (cf. [12, Conjecture 1]) that the inequality must be strict for non-hyperelliptic fibrations.

PROPOSITION 1. *Let $f : S \rightarrow B$ be a non-hyperelliptic fibration of genus $g \geq 3$, if $f_* \omega_{S/B}$ is strongly semi-stable, then*

$$K_{S/B}^2 \geq \frac{5g-6}{g} \deg(f_* \omega_{S/B}). \quad (3.1)$$

Proof. By Max Noether's theorem, the second multiplication map

$$\varrho : S^2 f_* \omega_{S/B} \rightarrow f_*(\omega_{S/B}^{\otimes 2})$$

is generically surjective for non-hyperelliptic fibrations $f : S \rightarrow B$. Let

$$S^2 f_* \omega_{S/B} \twoheadrightarrow \mathcal{F} := \varrho(S^2 f_* \omega_{S/B}) \subset f_*(\omega_{S/B}^{\otimes 2}).$$

Then \mathcal{F} is a vector bundle of rank $\text{rk}(f_*(\omega_{S/B}^{\otimes 2})) = 3g-3$, and

$$\deg(\mathcal{F}) \leq \deg(f_*(\omega_{S/B}^{\otimes 2})) = K_{S/B}^2 + \deg(f_* \omega_{S/B}). \quad (3.2)$$

On the other hand, semi-stability of $S^2 f_* \omega_{S/B}$ implies

$$\deg(\mathcal{F}) \geq (3g-3)\mu(S^2 f_* \omega_{S/B}) = \frac{6g-6}{g} \deg(f_* \omega_{S/B}). \quad (3.3)$$

Then (3.2) and (3.3) imply the required inequality (3.1). \square

If $E = f_*\omega_{S/B}$ is not strongly semi-stable, let

$$0 := E_0 \subset E_1 \subset E_2 \subset \cdots \subset E_{n-1} \subset \tilde{E} = F^{k*}E \quad (3.4)$$

be the Harder-Narasimhan filtration of $F^{k*}E$ with $r_i = \text{rk}(E_i)$ and

$$\mu_i = \mu(E_i/E_{i-1}) = \mu_{\min}(E_i) \quad (1 \leq i \leq n)$$

where we choose $k \geq k_0$ such that all quotients E_i/E_{i-1} appears in above filtration are strongly semi-stable. The second multiplication map induces a multiplication map, which is still denoted by ϱ ,

$$\varrho : S^2 \tilde{E} = F^{k*}S^2 f_*\omega_{S/B} \rightarrow F^{k*}f_*(\omega_{S/B}^{\otimes 2}).$$

Let $\tilde{\mathcal{F}} = F^{k*}\mathcal{F} = \varrho(S^2 \tilde{E}) \subset F^{k*}f_*(\omega_{S/B}^{\otimes 2})$ be the image of ϱ , then

$$K_{S/B}^2 \geq \frac{1}{p^k} \deg(\tilde{\mathcal{F}}) - \deg(f_*\omega_{S/B}).$$

Thus the question is to find a good lower bound of $\deg(\tilde{\mathcal{F}})$, where

$$0 \rightarrow \tilde{\mathcal{K}} := \ker(\varrho) \rightarrow S^2 \tilde{E} \xrightarrow{\varrho} \tilde{\mathcal{F}} \rightarrow 0.$$

Note that for any filtration

$$0 := \mathcal{F}_0 \subset \mathcal{F}_1 \subset \mathcal{F}_2 \subset \cdots \subset \mathcal{F}_{n-1} \subset \mathcal{F}_n := \tilde{\mathcal{F}} \quad (3.5)$$

of $\tilde{\mathcal{F}}$, $\deg(\mathcal{F}_i/\mathcal{F}_{i-1}) \geq (\text{rk}(\mathcal{F}_i) - \text{rk}(\mathcal{F}_{i-1}))\mu_{\min}(\mathcal{F}_i)$. If $\mu_{\min}(\mathcal{F}_i) \geq a_i$,

$$\deg(\tilde{\mathcal{F}}) \geq \sum_{i=1}^n \text{rk}(\mathcal{F}_i)(a_i - a_{i+1}). \quad (3.6)$$

One of choices of the filtration (3.5) is induced by the Harder-Narasimhan filtration (3.4) of $\tilde{E} = F^{k*}f_*\omega_{S/B}$ (similar with [7]):

$$\mathcal{F}_i = \varrho(E_i \otimes E_i) \subset \tilde{\mathcal{F}}.$$

The following lemma implies that $\mu_{\min}(\mathcal{F}_i) \geq 2\mu_i$ for all $1 \leq i \leq n$.

LEMMA 5. *Let \mathcal{E}_1 and \mathcal{E}_2 be two bundles over a smooth projective curve with all quotients in the Harder-Narasimhan of \mathcal{E}_1 and \mathcal{E}_2 are strongly semi-stable. Then we have*

$$\mu_{\min}(\mathcal{E}_1 \otimes \mathcal{E}_2) = \mu_{\min}(\mathcal{E}_1) + \mu_{\min}(\mathcal{E}_2).$$

Proof. It is clear that $\mu_{\min}(\mathcal{E}_1 \otimes \mathcal{E}_2) \leq \mu_{\min}(\mathcal{E}_1) + \mu_{\min}(\mathcal{E}_2)$ by [10, Proposition 3.5 (3)]. Thus is enough to show

$$\mu_{\min}(\mathcal{E}_1 \otimes \mathcal{E}_2) \geq \mu_{\min}(\mathcal{E}_1) + \mu_{\min}(\mathcal{E}_2).$$

By Lemma 3, there is a k_0 such that for all $k \geq k_0$, all quotients in the Harder-Narasimhan filtration of $F^{k*}(\mathcal{E}_1 \otimes \mathcal{E}_2)$ are strongly semi-stable.

Let $F^{k*}(\mathcal{E}_1 \otimes \mathcal{E}_2) \rightarrow \mathcal{Q}$ be the strongly semi-stable quotient with

$$\mu(\mathcal{Q}) = \mu_{\min}(F^{k*}(\mathcal{E}_1 \otimes \mathcal{E}_2)) \leq p^k \mu_{\min}(\mathcal{E}_1 \otimes \mathcal{E}_2).$$

Applying [10, Proposition 3.5(4)] on the nontrivial morphism

$$F^{k*}\mathcal{E}_1 \rightarrow (F^{k*}\mathcal{E}_2)^\vee \otimes \mathcal{Q},$$

we have $\mu_{\max}((F^{k*}\mathcal{E}_2)^\vee \otimes \mathcal{Q}) \geq \mu_{\min}(F^{k*}\mathcal{E}_1)$ and

$$\mu_{\max}((F^{k*}\mathcal{E}_2)^\vee \otimes \mathcal{Q}) = \mu(\mathcal{Q}) - \mu_{\min}(F^{k*}\mathcal{E}_2)$$

since all quotients $gr_i^{\text{HN}}(\mathcal{E}_2)$ and \mathcal{Q} are strongly semi-stable. Then

$$\mu(\mathcal{Q}) \geq \mu_{\min}(F^{k*}\mathcal{E}_1) + \mu_{\min}(F^{k*}\mathcal{E}_2) = p^k(\mu_{\min}(\mathcal{E}_1) + \mu_{\min}(\mathcal{E}_2)),$$

where the last equality holds since all $gr_i^{\text{HN}}(\mathcal{E}_1)$ and $gr_i^{\text{HN}}(\mathcal{E}_2)$ are strongly semi-stable, which implies that

$$\mu_{\min}(\mathcal{E}_1 \otimes \mathcal{E}_2) \geq \mu_{\min}(\mathcal{E}_1) + \mu_{\min}(\mathcal{E}_2).$$

□

A lemma of [7] provides the lower bound of $\text{rk}(\mathcal{F}_i)$. To state it, recall that in the proof of Theorem 6, each E_i defines a morphism

$$\phi_{L_i} : F \rightarrow \mathbb{P}^{r_i-1}$$

on the general fiber F of $f : S \rightarrow B$, where $L_i \subset \omega_F$ is generated by global sections $\{s_1, \dots, s_{r_i}\} \subset H^0(\mathcal{O}_S(K_{S/B})|_F) = H^0(\omega_F)$.

DEFINITION 2. Let $\tau_i : C_i \rightarrow \phi_{L_i}(F)$ be the normalization of $\phi_{L_i}(F)$,

$$g_i = g(C_i)$$

be the genus of C_i and $\psi_i : F \rightarrow C_i$ be the morphism such that

$$\phi_{L_i} = \tau_i \cdot \psi_i.$$

Let $c_i = \deg(\phi_{L_i}) = \deg(\psi_i)$. Then $c_i | c_{i-1}$ for all $1 \leq i \leq n$ and

$$r_1 < r_2 < \dots < r_{n-1} < r_n = g, \quad g_1 \leq g_2 \leq \dots \leq g_{n-1} \leq g_n = g.$$

LEMMA 6 ([7, Lemma 2.6]). For each $1 \leq i \leq n$, we have

$$\text{rk}(\mathcal{F}_i) \geq \begin{cases} 3r_i - 3, & \text{if } r_i \leq g_i + 1; \\ 2r_i + g_i - 1, & \text{if } r_i \geq g_i + 2. \end{cases}$$

In particular, if ϕ_{L_i} is a birational morphism, then

$$\text{rk}(\mathcal{F}_i) \geq 3r_i - 3.$$

LEMMA 7. Let d'_i be the degree of $\phi_{L_i}(F) \subset \mathbb{P}^{r_i-1}$, $\ell = \min\{i \mid c_i = 1\}$,

$$I = \{1 \leq i \leq \ell - 1 \mid r_i \geq g_i + 2\}.$$

Then we have

$$p^k K_{S/B}^2 \geq \sum_{i \in I} (3r_i + 2g_i - 2)(\mu_i - \mu_{i+1}) + \sum_{i \notin I} (5r_i - 6)(\mu_i - \mu_{i+1}),$$

$$p^k K_{S/B}^2 \geq 2 \sum_{i \in I} c_i d'_i (\mu_i - \mu_{i+1}) + \sum_{i \notin I} (4r_i - 2)(\mu_i - \mu_{i+1}) - 2\mu_n.$$

Proof. The first inequality is from (3.6) by taking $a_i = 2\mu_i$ and using estimate of $\text{rk}(\mathcal{F}_i)$ in Lemma 6. The second inequality is from

$$p^{2k} K_{S/B}^2 \geq \sum_{i=1}^{n-1} (d_i + d_{i+1})(\mu_i - \mu_{i+1}) + p^k (4g - 4)\mu_n$$

by using $d_i \leq d_{i+1}$, $d_i = p^k c_i d'_i$ and $c_i d'_i \geq 2r_i - 2$. \square

PROPOSITION 2. If $\min\{c_i \mid i \in I\} \geq 3$, then

$$K_{S/B}^2 \geq \frac{9(g-1)}{2(g+1)} \deg f_* \omega_{S/B}.$$

Proof. When $\min\{c_i \mid i \in I\} \geq 3$, use $d'_i \geq r_i - 1$ and Lemma 7,

$$p^k K_{S/B}^2 \geq \sum_{i \in I} (3r_i - 2)(\mu_i - \mu_{i+1}) + \sum_{i \notin I} (5r_i - 6)(\mu_i - \mu_{i+1}),$$

$$p^k K_{S/B}^2 \geq \sum_{i \in I} (6r_i - 6)(\mu_i - \mu_{i+1}) + \sum_{i \notin I} (4r_i - 2)(\mu_i - \mu_{i+1}) - 2\mu_n.$$

Take the average of above two inequalities, we have

$$K_{S/B}^2 \geq \frac{9}{2} \deg f_* \omega_{S/B} - \frac{4\mu_1 + \mu_n}{p^k}. \quad (3.7)$$

On the other hand, by Lemma 1, we have $K_{S/B}^2 \geq \frac{(2g-2)(\mu_1 + \mu_n)}{p^k}$ and $K_{S/B}^2 \geq \frac{2g-2}{p^k} \mu_1$, which and (3.7) implies the required inequality. \square

PROPOSITION 3. If $\min\{c_i \mid i \in I\} = 2$ and $g_i \geq \frac{g-1}{4}$ for $i \in I$ with $c_i = 2$. Then we have

$$K_{S/B}^2 > \frac{9(g-1)}{2(g+1)} \deg f_* \omega_{S/B}.$$

Proof. It is a matter to estimate d'_i . Since $\phi_{L_i}(F) \subset \mathbb{P}^{r_i-1}$ is an irreducible non-degenerate curve of degree d'_i , we have in general $d'_i \geq r_i - 1$ and more precisely the so called Castelnuovo's bound

$$d'_i - 1 \geq \frac{g_i}{m_i} + \frac{m_i + 1}{2}(r_i - 2)$$

where $m_i = \lceil \frac{d'_i - 1}{r_i - 2} \rceil$ is the positive integer defined by $d'_i - 1 = m_i(r_i - 2) + \varepsilon_i$ with $0 \leq \varepsilon_i < 1$ (see [1, Chapter III, 2]).

Let $I_1 = \{i \in I \mid c_i = 2\}$. Then for any $i \in I_1$, $d'_i \geq r_i - 1 + g_i$ by Castelnuovo's bound (since $r_i \geq g_i + 2 \geq 2$). On the other hand,

$$8g_i \geq 2g - 2 \geq 2d'_i \geq 2r_i - 2 + 2g_i$$

implies that $3g_i \geq r_i - 1$, which implies that

$$(3r_i + 2g_i - 2) + 2c_id'_i \geq 9r_i - 8, \quad \forall i \in I_1,$$

thus $(3r_i + 2g_i - 2) + 2c_id'_i \geq 9r_i - 8$ for all $i \in I$. Then the required inequality follows the same arguments in Proposition 2. \square

PROPOSITION 4 ([3, Theorem 3.1, 3.2]). *If there is an $i \in I$ such that $c_i = 2$ and $g_i < \frac{g-1}{4}$. Then*

$$K_{S/B}^2 \geq \frac{4(g-1)}{g-g_i} \deg f_* \omega_{S/B}.$$

Proof of Theorem 3. When $n = 1$ (i.e. $f_* \omega_{S/B}$ strongly semi-stable), Theorem 3 is true by Proposition 1. When $n > 1$, Theorem 3 is a consequence of Proposition 2, Proposition 3 and Proposition 4 since we have $g_i \geq 1$ if $c_i = 2$. \square
